## **ABSTRACT**

In this paper a novel local blur estimation method is presented. The focal blur process is usually modeled as a Gaussian low-pass filtering and then the problem of blur estimation is to identify the Gaussian blur kernel. In the proposed method, the blurred input image is first re-blurred by Gaussian blur kernels with different blur radii. Then the difference ratios between the multiple re-blurred images and the input image are used to determine the unknown blur radius. We show that the proposed method does not require edge detection pre-processing and can estimate a wide range of blur radius. Experimental results of the proposed method on both synthetic and natural images and a comparison with a state-of-the-art method are presented.

### 1. INTRODUCTION

Focal blur, or out-of-focus blur in images and videos occurs when objects in the scene are placed out of the focal range of the camera [1]. This is often used by photographers to draw the viewers' attention to objects in focus, but in many cases it is desirable to remove the blur and restore the original scene faithfully. As objects at varying distances show a different amount of blur in the image, accurate blur estimation is essential. The estimation of focal blur has also become an important topic in many other applications, such as restoring the blurred background part of images and videos, digital autofocusing systems and the 2D to 3D image conversion [3].

Focal blur is usually modeled as Gaussian blurring [2]. Therefore, the problem of blur estimation is to identify the Gaussian point spread function (PSF). Many techniques have been proposed to address the problem. Early blur estimation methods examine the regular pattern of zeros from the blurred image in the frequency domain. These methods can only identify a certain class of PSFs, but not truncated Gaussian PSFs which do not have zeros in the frequency domain. More recently parametric methods based on autoregressive moving-average (ARMA) models have been proposed [4] [5]. The

blur estimation becomes the identification of the ARMA model and a maximum likelihood (ML) estimation algorithm is employed for the estimation. However these methods are computationally intensive and lack a direct solution for the estimation. Recently, a blur estimation method from the work of Elder [6] receives considerable attention [7] [8]. In Elder's method, the blurred edge signal is convolved with a filter that is the second derivative of a Gaussian function and the response has a positive and a negative peak. The distance between these peak positions is used to determine the blur radius. A problem of Elder's method is that the blur estimation is easily deteriorated by the response of neighboring edges.

In this paper, we propose a new blur estimation method based on the difference between re-blurred versions of an image. Through an analysis performed on an edge model, we show that the blur radius can be easily calculated from the difference ratio, independent from the edge amplitude or position. The observation shows that the maximum of the difference ratio appears at the edge position. This suggests that the proposed blur estimation does not require the detection of edge position and angle. Furthermore, the proposed method demonstrates robust estimation even in areas with multiple neighboring edges. Experimental results on synthetic and natural images of the proposed method show favorable results.

The rest of the paper is organized as follows. In Section 2, we present the proposed blur estimation algorithm and its analysis based on an ideal edge model. Section 3 shows some experimental results on both synthetic and natural images and a comparison with Elder's method. Finally, we draw our conclusion in Section 4.

# 2. THE PROPOSED ALGORITHM

We introduce our proposed blur estimation algorithm based on an ideal edge and a blur kernel. The edge is modeled as a step function with amplitude A and offset B. For a discrete signal, the edge f(x) shown in Fig. 1 is

$$f(x) = \begin{cases} A+B, & x \ge 0 \\ B, & x < 0 \end{cases}, x \in \mathbb{Z}$$
 (1)

where x is the position. The focal blur kernel is modeled by

**Fig. 1**. The step edge f(x), the blurred edge b(x) and its two re-blurred versions  $b_a(x), b_b(x)$ 

the normalized Gaussian function:

$$g(n,\sigma) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{n^2}{2\sigma^2}\right), n \in \mathbb{Z}$$
 (2)

where  $\sigma$  is the unknown blur radius to be estimated. For the normalized Gaussian function, we have:

$$\sum_{n \in \mathbb{Z}} g(n, \sigma) = \sum_{n \in \mathbb{Z}} \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{n^2}{2\sigma^2}\right) = 1, \sigma > 0.5 \quad (3)$$

Then the blurred edge b(x) will be:

$$b(x) = \sum_{n \in \mathbb{Z}} f(x - n)g(n, \sigma)$$

$$= \begin{cases} \frac{A}{2}(1 + \sum_{n = -x}^{x} g(n, \sigma)) + B, & x \ge 0\\ \frac{A}{2}(1 - \sum_{n = x+1}^{x} g(n, \sigma)) + B, & x < 0 \end{cases}, x \in \mathbb{Z} \quad (4)$$

As the convolution of two Gaussian functions with blur radiuses  $\sigma_1$ ,  $\sigma_2$  is:

$$g(n, \sigma_1) * g(n, \sigma_2) = g(n, \sqrt{\sigma_1^2 + \sigma_2^2})$$
 (5)

re-blurring the blurred edge using Gaussian blur kernels with blur radius  $\sigma_a$  and  $\sigma_b$  ( $\sigma_b > \sigma_a$ ), results in two re-blurred versions  $b_a(x)$  and  $b_b(x)$ :

$$b_a(x) = \begin{cases} \frac{A}{2}(1+\sum_{\substack{n=-x\\-x-1}}^x g(n,\sqrt{\sigma^2+\sigma_a^2})) + B, & x \geq 0 \\ \frac{A}{2}(1-\sum_{\substack{n=x+1}}^x g(n,\sqrt{\sigma^2+\sigma_a^2})) + B, & x < 0 \end{cases}, \qquad r(x)_{max} = r(-1) = r(0) = \frac{\frac{1}{\sigma} - \frac{1}{\sqrt{\sigma^2+\sigma_a^2}}}{\frac{1}{\sqrt{\sigma^2+\sigma_a^2}} - \frac{1}{\sqrt{\sigma^2+\sigma_b^2}}}, \qquad \text{When } \sigma_a, \sigma_b \gg \sigma, \text{ we can use some approximations:}$$

Fig. 2. Difference ratio among the edge

$$b_b(x) = \begin{cases} \frac{A}{2} (1 + \sum_{n=-x}^{x} g(n, \sqrt{\sigma^2 + \sigma_b^2})) + B, & x \ge 0 \\ \frac{A}{2} (1 - \sum_{n=x+1}^{x} g(n, \sqrt{\sigma^2 + \sigma_b^2})) + B, & x < 0 \end{cases},$$

$$x \in \mathbb{Z}$$
 (6)

To make the blur estimation independent of the amplitude and offset of edges, we calculate the ratio r(x) of the differences between the original blurred edge and the two re-blurred versions for every position x:

$$x) = \sum_{n \in \mathbb{Z}} f(x - n)g(n, \sigma) \qquad r(x) = \frac{b(x) - b_a(x)}{b_a(x) - b_b(x)} = \begin{cases} \frac{A}{2}(1 + \sum_{n = -x}^{x} g(n, \sigma)) + B, & x \ge 0 \\ \frac{A}{2}(1 - \sum_{n = x + 1}^{x} g(n, \sigma)) + B, & x < 0 \end{cases}$$

$$x \in \mathbb{Z} \qquad (4) \qquad \begin{cases} \sum_{n = -x}^{x} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = -x}^{x} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = -x}^{x} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = -x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right) \\ \sum_{n = x + 1}^{-x - 1} \left(g(n, \sqrt{\sigma^2 + \sigma_a^2}) - g(n, \sigma)\right)$$

The difference ratio peaks at the edge position x = -1 and x = 0 as shown in Fig. 2. So we obtain:

$$r(x)_{max} = r(-1) = r(0) = \frac{\frac{1}{\sigma} - \frac{1}{\sqrt{\sigma^2 + \sigma_a^2}}}{\frac{1}{\sqrt{\sigma^2 + \sigma_a^2}} - \frac{1}{\sqrt{\sigma^2 + \sigma_b^2}}}$$
 (8)

$$\sqrt{\sigma^2 + \sigma_a^2} \approx \sigma_a$$

$$\sqrt{\sigma^2 + \sigma_b^2} pprox \sigma_b$$

which we use to simplify Equation 8:

$$r(x)_{max} \approx \frac{\frac{1}{\sigma} - \frac{1}{\sigma_a}}{\frac{1}{\sigma_a} - \frac{1}{\sigma_b}} = \frac{\left(\frac{\sigma_a}{\sigma} - 1\right) \cdot \sigma_b}{\sigma_b - \sigma_a} \tag{9}$$

or

$$\sigma \approx \frac{\sigma_a \cdot \sigma_b}{(\sigma_b - \sigma_a) \cdot r(x)_{max} + \sigma_b} \tag{10}$$

Equation 8-10 shows that blur radius  $\sigma$  can be calculated from the difference ratio maximum  $r(x)_{max}$  and re-blur radius  $\sigma_a$ ,  $\sigma_b$ , independent of the edge amplitude A and offset B. The identification of the local maximum of difference ratio  $r(x)_{max}$  can not only estimate the blur radius but also locate the edge position, which implies the blur estimation does not require any edge detection pre-processing. This helps to keep the complexity low for the blur estimation in 2D images, we use a 2D Gaussian blur kernel for the re-blurring. As any direction of a 2D Gaussian function is a 1D Gaussian function, the proposed blur estimation is also applicable. Using 2D Gaussian kernels for the estimation avoids detecting the angle of the edge or gradient, which is required in Elder's method.

#### 3. EXPERIMENTS AND RESULTS

In this section, we test the proposed method on some synthetic and natural images, and we compare that with Elder's methods. For the synthetic images, we use multiple step edges blurred by a 1D Gaussian blur kernel, with the blur radius increasing linearly along the edge from 0.1 to 5, as shown in Fig. 3. About one percent Gaussian noise is added to simulate sensor noise. Different distances between neighboring step edges D have been used. We use the optimal settings for both

Fig. 3. Synthetic images

methods and the results are shown in Fig. 4 and Fig. 5. As one can see, when the distance between neighboring edges is relative large (D=50 pixels) both methods can reliably estimate a wide range of blur radius. When the distance between

neighboring edges becomes relative small (D=20 pixels), Elder's method suffers considerably from the interference of neighboring edges and the estimation is very unreliable while the propose method demonstrates better estimates.

Fig. 4. Estimated blur radius on the synthetic image with D=50 pixels for Elder's method and the proposed method

Fig. 5. Estimated blur radius on the synthetic image with D=20 pixels for Elder's method and the proposed method

For natural images, we use the image Lena (Fig. 6) for the test. Blur estimation results of Elder's method and the proposed method have been illustrated in grey images (Fig. 7). Both methods are implemented in a block-based manner. A block size of  $8\times 8$  pixels has been used and we assume that the blur radius is the same within the block. In the blur estimation results, the lighter areas indicate a larger blur radius, while the darker areas indicate a smaller blur radius. We can see that the differently blurred background of the image Lena has been estimated more accurately by the proposed method than by Elder's method. Note that Lena's face and shoulder show strong *shading blur*. Both methods can estimate the blur radius but they cannot distinguish the shading blur from the focal blur.

**Fig. 7**. Estimation results: the lighter areas indicate a larger blur radius, while the darker areas indicate a smaller blur radius. (A) Result of Elder's method. (B) Results of the proposed method.

# 4. CONCLUSION

We have presented a novel robust, low-cost blur estimation algorithm. The maximum of the difference ratio between an original image and its two re-blurred versions has been proposed to identify the edges and estimate the blur radius in the original image. The proposed method has been shown to have robust estimation, especially for the interference from neighboring edges. It also features easy implementation and merits further attention.
